Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

43 **Abstract**

44
45 The biomass, generated after the lipid extraction from *Nannochloropsis* microalgae
46 (LEM) for biodiesel production, demonstrated their suitability for both energy and
47 nutrients recovery. The anaerobic digestion of LEM produced a minimum of 268
48 mL_{CH₄}/g_{VS} in different experiments. The co-digestion of LEM and sewage sludge
49 revealed that both waste can be co-digested without inhibition, although no synergy was
50
51
52
53
54
55

58
59
60

1
2
3 observed. The methane yields barely increased 10% after pre-treatments (ultrasound and
4
5 ultrasound combined with alkali addition).
6

7 Regarding bio-oil production from hydrothermal liquefaction process, more than 28%
8
9 of the LEM was converted into bio-oil. Moreover, the aqueous phase generated during
10
11 the bio-oil production was successfully utilised as nitrogen source for microalgae
12
13 cultivation.

26
27 **INTRODUCTION**

28
29 Over the past years, researchers turned their attention to find renewable and cost-
30
31 effective feedstocks for biofuels, as a consequence of the predicted fossil-fuels reserves
32
33 depletion. Microalgae utilisation as feedstock was also fostered by the "food-versus-fuel
34
35 competition" derived from the biofuels production from crops [1]. Amongst the
36
37 different biofuels, biodiesel still gathers the attention of researchers. The process scale-
38
39 up is not economically viable nowadays [2], but increasing efforts are being made to
40
41 overcome the drawbacks. For example, the valorisation of the lipid-extracted
42
43 microalgae (LEM) may be beneficial for the biodiesel process. Approximately 65% of
44
45 the biomass remains as waste after lipid extraction, containing some valuable
46
47 compounds [3].
48
49

50
51 The anaerobic digestion (AD) is a well-known technology used for the stabilisation of
52
53 the sewage sludge generated in wastewater treatment plants (WWTPs). The versatility
54
55 of this process allows the treatment of a wide range of feedstocks, including microalgae.
56
57
58
59
60

1
2
3 In recent years, the LEM have been also considered as promising substrates for AD [3].
4
5 The low C to N ratio in microalgae, which can lead to AD inhibition, is even lower in
6
7 LEM. The anaerobic co-digestion (Aco-D) with sewage sludge is a viable alternative to
8
9 balance the C to N ratio. Additionally of being widely available, sewage sludge is the
10
11 second substrate utilised in co-digestion due to the over-sized digesters in WWTP [4].
12
13 The AD also offers the advantage of recycling nutrient. The aqueous phase generated
14
15 during AD, rich in ammonia and phosphorous, may be used for microalgae cultivation
16
17 [5,6]. On the other hand, the hydrothermal liquefaction (HTL) is a completely different
18
19 technology which converts microalgae and several microalgae waste into bio-oil [7-11].
20
21 The bio-oil, a liquid fuel, can be further combusted or upgraded. Similar to AD, the
22
23 HTL process generates a nutrients-rich aqueous phase (AP-HTL) which can be recycled
24
25 for microalgae cultivation [12-14].
26
27

28
29 This paper is the first attempt to evaluate several processing routes for the biofuels
30
31 production from LEM; the routes can be observed in the scheme presented in Figure 1.
32
33 Several options to avoid AD inhibition and to improve the methane production were
34
35 evaluated. The increased protein content after the lipid extraction and the presence of
36
37 sea salt in the LEM are potential causes of inhibition [3,15]. The effects of high
38
39 amounts of proteins were evaluated by setting several substrate to inoculum ratios (SIR)
40
41 in the experiments. Regarding sea salt, the influence of washing biomass was evaluated.
42
43 The LEM were also co-digested with sewage sludge, based on the advantages of
44
45 combining both substrates as previously mentioned. The last option consisted of
46
47 applying two pre-treatment methods to improve the methane production. The ultrasonic
48
49 pre-treatment was chosen based on the suitability to increase the biodegradability of
50
51 microalgae [16]. The combination of alkali addition and ultrasonic pre-treatment was
52
53 chosen based on the benefits when applied prior to the AD of some waste [17,18].
54
55
56
57
58
59
60

1
2
3 In a completely different processing route, the LEM was used as for HTL. Although the
4
5 process optimisation is not addressed in this report, the valorisation of the AP-HTL
6
7 generated was evaluated as nutrients source for microalgae cultivation. The bio-oil
8
9 production together with the nutrient recycling has not been reported yet.
10

11 12 13 14 **MATERIALS AND METHODS**

15 16 **Materials**

17
18 Lipid-extracted *Nannochloropsis oculata*, provided by AlgoSource's (Alpha Biotech,
19
20 Asserac, France), was generated from a lipid-extraction process with supercritical
21
22 carbon dioxide (SCCO₂). The solid LEM was stored in a desiccator until required. The
23
24 LEM was the substrate used for biofuels production via AD and HTL.

25
26 For the experiments where microalgae were cultivated in the aqueous phase recovered
27
28 from the HTL, the species was *Nannochloropsis gaditana* Lubián, strain CCMP 1775,
29
30 obtained from NCMA (National Center for Marine Algae), formerly CCMP.
31

32
33 The inoculum for the AD experiments consisted of digested sludge from a pilot-plant
34
35 under mesophilic conditions. The reactors were operated under semi-continuous
36
37 conditions and fed with a sewage sludge blend (primary and secondary sludge in ratio
38
39 65:35 v/v); the same sludge blend was utilised as substrate in the co-digestion
40
41 experiments. The sewage sludge blend was collected from the municipal WWTPs in
42
43 Reus (Tarragona, Spain).
44
45
46
47
48

49 50 **Experimental procedure**

51 52 *Analytical methods*

53
54 Total solids (TS), volatile solids (VS), protein and carbohydrate were analysed
55
56 according to the methods described in Caporgno et al. [19]. The residual lipid in the
57
58
59
60

1
2
3 LEM was determined by extraction of 3 g of LEM using a Soxhlet apparatus with a
4
5 reflux period of 7 hours and hexane as solvent; lipids were then recovered by solvent
6
7 evaporation and weighed. The TS content in the LEM was 928.8 ± 0.7 g/kg, with VS/TS
8
9 of 0.75 ± 0.01 . The organic fraction contained 61.7 ± 4.1 % proteins, 7.6 ± 0.1 % lipids and
10
11 25.3 ± 2.0 % carbohydrates. The TS content and the VS/TS were 27.8 ± 0.7 g/L and
12
13 0.76 ± 0.01 in sewage sludge, and 17.2 ± 1.0 g/L and 0.64 ± 0.02 in the inoculum.

14
15
16 In the AD experiments, biogas production and composition, volatile fatty acid
17
18 concentration (VFA), alkalinity, were determined as described in Caporgno et al. [19].
19

20
21 In the HTL experiments, the bio-oil was analysed by chromatography-mass
22
23 spectroscopy (GC-MS). The samples were subjected to GS-MS analysis
24
25 (G1099A/MSD5973) using a HP-5MS column (19091S-433) and helium as carrier gas
26
27 with flow rate of 1.4 mL/min. A volume of 1 μ L dichloromethane (DCM) extract was
28
29 injected at 280 °C with a split ratio of 2:1. The initial temperature in the oven was 80
30
31 °C, and after 1 min, it was increased at 15 °C/min until 200 °C. Subsequently, the
32
33 temperature was increased at 5 °C/min until 310 °C and held constant for 10 min. The
34
35 higher heating value (HHV) in bio-oil was determined in a bomb calorimeter
36
37 (Gallenkamp Ballistic Bomb Calorimeters), using benzoic acid as a standard substance.
38
39 On the other hand, the HHV of the LEM was calculated based on the elemental
40
41 composition of the biomass using the Dulong's formula as described in Vardon et al. [9]
42
43 due to the high content of ashes in the LEW. The ammonia nitrogen ($\text{NH}_3\text{-N}$), nitrate
44
45 nitrogen ($\text{NO}_3\text{-N}$), nitrite nitrogen ($\text{NO}_2\text{-N}$), phosphate phosphorus ($\text{PO}_4\text{-P}$), and
46
47 chemical oxygen demand (COD) were measured in the aqueous phase prior to the
48
49 microalgae cultivation, using a HI-83099-02 bench photometer and following the
50
51 procedures described in the user's manual (Hanna Instruments, 2014). The total
52
53 nitrogen (TN), total carbon (TC) and total inorganic carbon (TIC) were determined in
54
55
56
57
58
59
60

1
2
3 Multi NC 3100 (Analytic Jena) analyser. The gas-phase composition was analysed
4
5 using the method for the biogas analysis described in Caporgno et al. [19].
6

7 Carbon, hydrogen and nitrogen content in the LEM, the bio-oil and the solid waste
8
9 recovered after HTL have been analysed in an LECO TruSpec Elemental Analyser.
10
11 Oxygen content was determined by difference.
12

13
14 In the cultivation experiments, cell growth was monitored by measuring the absorbance
15
16 at 750 nm with a microplate reader (Infinite® M200 PRO, Tecan).
17
18

19 20 *Anaerobic digestion*

21
22 The batch reactors were set up following the procedure described in Caporgno et al.
23
24 [19]. The substrate depended on the experiment. The effects of washing the LEM and
25
26 the SIR variation were simultaneously evaluated. In the washing step, 20 g of LEM
27
28 were mixed with 200 mL deionised water at room temperature, stirred 20 min and then
29
30 centrifuged to recover the solid fraction; the procedure was repeated three times.
31
32 Reactors with SIRs of 1:4, 1:2 and 1:1 $VS_{\text{Substrate}}:VS_{\text{Inoculum}}$ were prepared with different
33
34 amounts of LEM, either washed or unwashed.
35
36

37
38 In the co-digestion experiments, the SIR was of 1:2 $VS_{\text{Substrate}}:VS_{\text{Inoculum}}$. Different
39
40 mixtures of sewage sludge and unwashed LEM were fed, replacing 25%, 50% and 75%
41
42 of the VS from LEM by VS from sewage sludge.
43
44

45
46 Two different pre-treatment methods were applied to unwashed LEM. The first one,
47
48 ultrasonic pre-treatment, consisted in applying three different energy levels: 28, 48 and
49
50 55 MJ/kg_{TS} at 24 kHz working frequency and 93 W ultrasonic power (UP200S
51
52 Hielscher Ultrasonics GmbH, Germany). The LEM were suspended in deionised water
53
54 for the pre-treatment. The pre-treatment was carried out at room temperature and using
55
56 a water bath to avoid the sample heating. The energy supplied was calculated according
57
58
59
60

1
2
3 to the ultrasonic power, the concentration of solids in the sample and the treatment
4 duration. The second pre-treatment consisted in combining addition of alkali and
5 ultrasound application at low-energy level. The energy applied during ultrasonic
6 disintegration was 17 MJ/kg_{TS}. The alkali pre-treatment consisted in adjusting the pH at
7 9, 11 and 13 with NaOH, and keeping the samples at room temperature for 24 h before
8 digestion. For the pre-treatment combination, the pH in the samples was first adjusted at
9 9, 11 and 13, and then the ultrasonic disintegration was applied. The pH in the pre-
10 treated samples was neutralised to pH 7 with HCl.
11
12
13
14
15
16
17
18
19
20
21

22 *Hydrothermal liquefaction*

23
24 The experiments were performed at 300 °C, ≈10 MPa, 30 min retention time in a 1L
25 reactor (1 Liter EZE-Seal Bolted Closure, Autoclave Engineers). The reactor was
26 loaded with 300 g of slurry, containing 20% LEM in water (w/w), and then purged with
27 nitrogen to remove the oxygen before heating. The different product fractions were
28 recovered (Figure 2) and analysed. After the reactor was cooled down to room
29 temperature, the gases were vented off and collected in gas sampling bags for further
30 analysis. The major part of AP-HTL was removed by pouring it into a beaker.
31 Dichloromethane (DCM) was used as solvent to recover the bio-oil, which was adhered
32 to the reactor walls. The DCM containing the bio-oil was separated from the remaining
33 aqueous fraction using a separatory funnel. Both AP-HTL and DCM were vacuum-
34 filtered through pre-weighted filters for the quantification of the amount of suspended
35 solids. DCM was dried under anhydrous sodium sulphate and evaporated in a rotary
36 evaporator to determine the amount of bio-oil. The AP-HTL was recovered and used for
37 microalgae cultivation.
38
39
40
41
42
43
44
45
46
47

51
52
53
54
55
56
57
58
59
60

1
2
3 For the mass balance, the products yields were defined as weight percentages relative to
4 the raw material. The bio-oil yield accounted the DCM-soluble fraction, the AP-HTL
5 accounted dissolved constituents remaining after the DCM extraction, the solid fraction
6 accounted the mass of dried particulates retained after filtration, and finally, the gas-
7 phase yield was calculated by difference.
8
9
10
11
12

13 14 15 16 *Nutrients recycling*

17
18 A growth experiment was performed to evaluate the feasibility of replacing the nitrogen
19 source in the algal culture medium by the aqueous phase from HTL. *N gaditana* was
20 cultivated in culture media containing different proportions of AP-HTL. Blank assays
21 were performed with seawater enriched with a modification of Guillard's f/2
22 formulation [20]. Since f/2 is a rather diluted medium for biomass production purposes,
23 nitrogen and phosphorous concentrations in this modified medium (f/2⁺) were increased
24 up to 60 mg N-NO₃/L and to reach a molar N:P ratio equal to 16:1. Based on the total
25 nitrogen in AP-HTL, five different mixtures of AP-HTL and f/2⁺ were prepared by the
26 replacement of 7, 15, 30, 45 and 60 mg N/L in the f/2⁺ medium by the AP-HTL
27 addition. Media were filter sterilized through 0.2 μm.

36
37
38
39

40
41 Microalgae were cultured in sterile 6-well microplates, with a working volume of 3 mL
42 per well and an initial microalgae density of 3·10⁵ cells/mL. Triplicate cultures were
43 grown in continuous agitation at 25±1°C, under an irradiance of ca. 115 μmol
44 photons/m²·s at the surface of the microplates, provided by daylight fluorescent lamps
45 in a 16:8 light:dark cycle.
46
47
48
49
50

51
52 Microalgae growth was daily monitored by light absorbance measurements, at 750 nm,
53 with a M200Pro Infinite Tecan microplate reader. Division rates (k) were obtained by
54
55
56
57
58
59
60

1
2
3 calculating the slope of the linear least-squares regression for the \log_2 -transformed
4
5 values of the sample absorbance at 750 nm during the exponential growth phase [21].
6
7

8 9 **RESULTS AND DISCUSSION**

10 **Anaerobic digestion**

11
12 Table 1 summarises the ultimate methane productions obtained in all the digestion
13
14 experiments, the kind of substrate fed and the SIR used in the reactors. It is worth
15
16 mentioning that the experiments were not performed simultaneously, therefore the
17
18 methane productions from LEM slightly differ in some of the experiments.
19
20
21
22
23

24 *LEM washing and SIR variation*

25
26 The ultimate methane productions from washed and unwashed LEM indicated that the
27
28 washing influenced the AD negatively. The methane production decreased between
29
30 29% and 34% after washing. The salt concentration in marine microalgae can strongly
31
32 affect the methane production [15]; however, the washing removed not only salts from
33
34 the biomass. The analysis of the washing water revealed that $67\pm 1\%$ of the solids
35
36 fraction removed was constituted by organic compounds. The loss of these organics
37
38 caused the significant reduction in the methane production [22]. Moreover, not only the
39
40 organic fraction content was affected, but also the characteristics of the organic fraction.
41
42 As mentioned 2.2.2., the same amount of substrate on VS basis was fed in all the
43
44 reactors. For this reason, the lower methane production can not be attributed to the
45
46 organic fraction content in the digesters. Easily-biodegradable compounds were
47
48 removed by washing, thus decreasing the methane production from washed substrates.
49
50
51
52 Regarding the SIR, it was clearly demonstrated that the ratios evaluated cause no
53
54 influence on the digestion of washed and unwashed LEM (Table 1). The differences in
55
56
57
58
59
60

1
2
3 the ultimate methane production from washed LEM were less than 7%, and from
4
5 unwashed LEM, less than 2%. In the literature, 1:1 is commonly considered a SIR
6
7 threshold for inhibition; however, it depends on the substrate characteristics. Long chain
8
9 fatty acid, hydrolysis products of lipids, lead to inhibition during the AD of microalgae
10
11 with high lipid content. For this reason, the SIR can be increased in the digesters with
12
13 LEM [23]. Similarly, substrates characterised by high protein content cause inhibition
14
15 by ammonia during AD [3]. Ammonia is the most probable cause of inhibition due to
16
17 the high protein content in the LEM. The ammonia concentration, VFA concentration
18
19 and pH amongst other parameters indicated stable operation.
20
21

22
23 In reactors with unwashed LEM, the methane production throughout the first days of
24
25 the experiment was affected (Data not shown). These effects, observed at 1:1, were also
26
27 reported during the AD of other LEM [23,24]. The VFA were not simultaneously
28
29 converted into methane, leading to significant accumulation of VFA and methane
30
31 production decrease. The VFA accumulation can lead to inhibition; however, the VFA
32
33 accumulated but they were converted into methane soon afterwards. The ratio 1:1 was
34
35 close to the SIR threshold for inhibition. Regarding the washed LEM ~~LEW~~, the
36
37 phenomenon did not occur due to the low degradability of the organic fraction.
38
39
40
41
42

43 *LEM co-digestion with sewage sludge*

44
45 The ultimate methane production from LEM and sewage sludge co-digestion indicated
46
47 no synergy by mixing both substrates. The sewage sludge and the LEM produced the
48
49 highest and the lowest methane yields, 360 ± 12 mL_{CH₄}/g_{V_S} and 274 ± 4 mL_{CH₄}/g_{V_S}
50
51 respectively. The methane productions from the mixtures were proportional to the
52
53 percentage of each substrate in the mixture. Similar results were reported by Neumann
54
55 et al., who highlighted that the absence of inhibition allows mixing both substrates
56
57
58
59
60

1
2
3 without affecting the process operation [25]. The co-digestion with sewage sludge is
4
5 even more advantageous when considering the non-used capacity of the digesters in
6
7 WWTP, approximately 30% [4]. Recently, Astals et al. emphasised the benefits of
8
9 integrating pig manure processing and microalgae cultivation, in spite of the absence of
10
11 synergy in Aco-D [6].
12
13

14 15 16 LEM *pre-treatment*

17
18 The effects of the ultrasonic pre-treatment on the AD of LEM can be observed in Table
19
20 1. The lowest energy input (28 MJ/kg_{TS}) seemed to be inefficient to increase the LEM
21
22 degradation, since the methane production was similar to the obtained with untreated
23
24 LEM. Higher energy inputs (48 and 65 MJ/kg_{TS}) only resulted in a 7-9% increase in
25
26 methane production. Similar results were reported after ultrasonic pre-treatment of
27
28 *Nannochloropsis sp.* LEM [24]. The results suggest that this pre-treatment was probably
29
30 unsuitable for microalgae wastes from the genus *Nannochloropsis*, probably due to the
31
32 cell wall characteristics. The cell wall in the genus *Nannochloropsis* has a cellulosic
33
34 inner-wall protected by an outer hydrophobic algaenan layer [26], which hampers AD
35
36 degradation [27]. For this reason, powerful pre-treatment methods have been suggested
37
38 for *Nannochloropsis* species [27].
39
40
41
42

43 In order to improve the limited degradation of the LEM, an ultrasonic pre-treatment
44
45 with low-energy input was combined with alkali addition. For comparison, the effects
46
47 of alkali and ultrasound were also separately tested. The first visible effects of the pre-
48
49 treatment were noticed in the LEM composition. Alkali treatment caused organic matter
50
51 destruction in the LEM, so that after the pre-treatment with alkali addition up to pH 13
52
53 the VS/TS ratio decreased from 0.75 to 0.62. Likewise, the combined pre-treatment
54
55 decreased the VS/TS ratio down to 0.66. Similar VS/TS decreases reported during the
56
57
58
59
60

1
2
3 alkali and ultrasonic pre-treatment of other substrates were attributed to the
4 mineralization of some components [28]. Pre-treatment with alkali also increased the
5 methane production up to 8% (Table 1), the highest methane production being obtained
6 with the lowest NaOH dosage. The pre-treatment of undamaged microalgae with similar
7 NaOH dosages also gave higher methane productions with lower dosages [29].
8 Furthermore, the highest methane production was obtained from the non pre-treated
9 microalgae [29]. Regarding the ultrasonic pre-treatment (17 MJ/kg_{TS}), the methane
10 production remained unchanged, as expected considering the inefficiency of a stronger
11 input (28 MJ/kg_{TS}) discussed at the beginning of this section. Surprisingly, the pre-
12 treatment combination did not increase the methane production (Table 1). References
13 regarding the AD of LEM are currently scarce, especially those focused on the effects
14 of pre-treatments. Only Suresh et al. reported an alkali pre-treatment of LEM and its
15 combination with ultrasonication. The authors suggested inhibition due to VFA
16 accumulation, being the methane production negatively affected [30]. However, in the
17 present work, the absence of inhibition was corroborated in all the reactors at the end of
18 experiments. On the other hand, the combined pre-treatment applied to other
19 lignocellulosic substrates did not affect the total methane production [28]. The alkaline
20 pre-treatment affects the intermolecular linkages and functional groups of lignin,
21 cellulose, and hemicellulose [31]. The cell walls structures are more vulnerable to the
22 shear forces in the ultrasonic pre-treatment when the pre-treatments are combined.
23 However, the effectiveness of the alkaline pre-treatment is considered dependent on the
24 content of lignin in the biomass and the content of lignin in microalgae is considered
25 low [31].

56 **Hydrothermal liquefaction**

57
58
59
60

1
2
3 The mass balance allows establishing the product distribution after the HTL process.

4
5 The results, presented in Table 2, indicated that similar amounts of the biomass were
6
7 distributed between the bio-oil, the AP-HTL, the gas and the solid fraction.
8

9
10 The bio-oil showed the highest yield, 28 ± 2 g/100g_{LEM}. This yield is comparable to the
11
12 obtained by processing *Scenedesmus sp.* LEM, with high-protein and low-lipid content,
13
14 under the same experimental conditions [9]. Higher bio-oil yields have been obtained
15

16 from *N. salina* LEM [10], but with a high amount of residual lipids (≈ 20 g/100g_{sample}).
17
18 Bio-oil yields close to 45 g/100g_{sample} have been recently reported from protein-
19
20 extracted *Scenedesmus sp.* [11]; once again, the lipid fraction which remains after
21
22 extracting the proteins (≈ 18.5 g/100g_{sample}) may contribute to the high bio-oil yield.
23
24

25 Lipids present the highest bio-oil yield, followed by proteins and carbohydrates [12].
26

27 On the other hand, the bio-oil obtained by processing *D. tertiolecta* from β -carotene
28
29 production yielded approximately 5 g/100g_{sample} under operating conditions similar to
30
31 the present experiments; quite severe operating conditions were required to increase the
32
33 bio-oil yield [7]. The bio-oil yields obtained in the experiments here reported are also
34
35 comparable with the reported in the literature, after processing from the whole
36
37 *Nannochloropsis oculata*, in spite of the differences in the lipid content [12]. It worth
38
39 mentioning that bio-oil yield was calculated on the dry weight basis of the LEW; the
40
41 yield increases when is calculated on the dry ash-free basis due to the high content of
42
43 ashes in the LEM.
44
45

46
47 Regarding the characteristics of the bio-oil, the analysis of the HHV resulted in
48
49 37.2 ± 0.9 MJ/kg, which is in agreement with the values reported for other LEM under
50
51 the same experimental conditions [9] and other microalgae species under different HTL
52
53 conditions [8,12]. The HHV was considerably low for the LEM, 17.7 ± 0.1 MJ/kg,
54
55 mainly as a consequence of the high content of ashes in the LEW. The qualitative GC-
56
57
58
59
60

1
2
3 MS analysis of the bio-oil evidenced its complexity. The high protein content in the
4 LEM led to the presence of nitrogenous compounds in the bio-oil. The main compounds
5 can be included in the category of aromatic compounds such as indole derivatives or in
6 the category of highly aliphatic compounds, including long chain alkanes and alkenes,
7 free fatty acids and amide derivatives. Similar compounds have been also identified by
8 other authors [7,9,11]. The analysis elemental of the bio-oil determined C, H, N and O
9 percentages of 70%, 9%, 5% and 17% respectively. According to these results, the bio-
10 oil quality is better than the reported by Vardon et al. [9] and comparable to the bio-oil
11 quality reported by Zhu et al. [10] in terms of N and O contents. The analysis elemental
12 of the LEM determined C, H, N and O percentages of 40%, 6%, 5% and 24%
13 respectively. Based on these results, 48±4% of the C from the LEM was converted into
14 bio-oil, similar to value reported by Vardon et al. [9].

60
The gas yields indicated that a large portion of the initial biomass was converted into
gaseous products. Although the gas composition was not analysed in detail, the
chromatogram revealed that the gas fraction was mainly CO₂ and small amounts of
simple hydrocarbons as it was expected based on the literature [8,11]. The high content
of CO₂ suggests the possibility of using the exhausted gas in the microalgae cultivation
unit [32].

The yield of the solid fraction was considerably higher than the yields obtained after
processing LEM under similar experimental conditions [9,11]. Comparable yields of the
solid fraction were reported during the HTL of *Dunaliella tertiolecta* waste, but in this
case, the bio-oil yield indicates low biomass conversion [7]. As mentioned before, the
LEM here used was characterised by high ashes content, and most of the ashes
contributed to increase the yield of the solid fraction. The analysis of the solid fraction
revealed the presence of the major part of the inorganic fraction from the LEM, 78±3%.

1
2
3 The analysis elemental of the solid determined C, H, N and O percentages of 78%, 12%,
4
5 4% and 6% respectively. The high percentage of C and the appearance of the solids,
6
7 suggest the formation of bio-char as a consequence of the re-polymerisation and
8
9 carbonisation of water-soluble compounds derived mainly from carbohydrates, due to
10
11 the high temperature in the process [33]. Based on the percentages of ashes and C in the
12
13 solid fraction, it can be stated that a considerable high biomass conversion was achieved
14
15 during the process.
16

17
18 The mass balance revealed that the AP-HTL contained a high percentage of the
19
20 inorganic fraction originally present in the LEM, but also organic compounds. The
21
22 COD and the TOC analysis resulted in 75500 mg O₂/L and 21450 mg C/L respectively,
23
24 in agreement with the concentrations reported in the literature [13,34]. The COD and
25
26 TOC values indicate the presence of dissolved organic compound. Although the
27
28 compounds were not identified, they may be formic acid, acetic acid, lactic acid,
29
30 glycerol amongst other are some polar organic compounds which remained solubilised
31
32 in water [35]. As can be seen in Table 2, 26±1% of the C from the LEM remained
33
34 solubilised in the AP-HTL. Based on the high protein content, its decomposition can
35
36 generate nitrogen compounds such as pyroles, indoles and phenols [12]. The nitrogen
37
38 content was approximately 7000 mg N/L, and around 68% of the TN was in the form of
39
40 NH₄⁺. The major part of the N from the LEM remained solubilised in the AP-HTL
41
42 (Table 2). The C to N ratio resulted ≈3.4 in the aqueous phase, as reported during the
43
44 HTL of several microalgae species under similar experimental conditions [8,12,14]. The
45
46 PO₄⁻³ was 90 mg P/L, considerably low compared with the N and C concentrations. The
47
48 phosphorous distribution in the HTL products can be affected by reaction temperature
49
50 and retention time, and by the reaction between the amino acids with reducing sugar
51
52 [13].
53
54
55
56
57
58
59
60

1
2
3 As mentioned before, the optimisation of the HTL process was not studied in this
4 manuscript. However, the production of bio-oil from LEM and the subsequent
5 upgrading process was already reported by Zhu et al. [10]. The similarities in the
6 composition of the biomass and the yields and characteristics of the bio-oil suggest that
7 the HTL of lipid-extracted *N. oculata* may be also a promising alternative to produce
8 liquid fuels which can compete with conventional fossil fuels. Moreover, the nutrient
9 recycling can significantly contribute to improve economic aspects.

20 **Nutrients recycling**

21
22 The suitability of the AP-HTL for microalgae cultivation was evaluated. According to
23 the nutrient analysis performed, the N:P ratio of the AP-HTL was 78:1. Such a high N:P
24 ratio is far from the optimal N:P ratios for microalgae development [36]; this was
25 confirmed by the low *Nannochloropsis gaditana* growth on dilutions of AP-HTL in a
26 previous culture experiment (data not shown). Therefore, it was decided to check the
27 suitability of the AP-HTL only as nitrogen source. With this aim, part or the entire N-
28 NO₃ source of the standard medium was substituted by a volume of AP-HTL that
29 provided with an equal amount of nitrogen. Several AP-HTL loads were tested
30 considering that a high AP-HTL concentration could have an inhibitory effect on the
31 culture due to toxic compounds such as amides or heterocyclic compounds [13].
32
33
34
35
36
37
38
39
40
41
42
43
44

45 Figure 3 shows *N. gaditana* growth curves for different loads of AP-HTL; the curves
46 are plotted in semi-logarithmic scale for better visualisation of the exponential-growth
47 phase. The amount of AP-HTL that accounted for the total substitution of N-NO₃
48 (HTL60) inhibited growth from the beginning, as evidenced by the reduced division rate
49 (Table 3) and the final biomass which was 25% of the obtained in the standard medium.
50
51
52
53
54
55
56
57
58
59
60 On the contrary, AP-HTL loads contributing up to 30 mg N (HTL30) supported growths

1
2
3 only slightly smaller than in the standard medium. Division rates were similar or even
4
5 slightly higher than in the standard medium, but at the end, final biomass (in terms of
6
7 Abs_{750nm}) was 90-77% of that obtained in standard medium, the higher the final biomass
8
9 the lower the AP-HTL load.

10
11 The applicability of an AP-HTL as microalgae culture medium depends on the
12
13 concentration and form of macro- (nitrogen, phosphorus, N:P ratio) and micro- nutrients
14
15 [37], the absence of harmful compounds [12,34,38], the pH [14] and the microalgae
16
17 species used [12,14]. In the present experiments, the growth inhibition at HTL60
18
19 concentrations may reflect a compound at harmful concentration rather than the form of
20
21 inorganic N supplied. Although high amounts of NH_4^+ are known to be toxic [39], *N.*
22
23 *gaditana* has demonstrated to thrive at concentrations up to 190 mg N- NH_4^+ /L when the
24
25 pH of the culture is controlled at 8.0 [40]. Therefore, the 60 mg N- NH_4^+ /L in HTL60 at
26
27 the initial pH of 8.3 (Table 3) should not be harmful.

28
29 The AP-HTL contributing up to 30 mg N (HTL30) supports growth close to the
30
31 maximum growth obtained with standard medium. Further experiments are needed to
32
33 ascertain which other nutrients, such as iron and other micronutrients, can be substituted
34
35 from standard media by AP-HTL.

36 37 38 39 40 41 42 43 **CONCLUSIONS**

44
45 This study demonstrated the valorisation of the (lipid-extracted *Nannochloropsis* can be
46
47 carried out producing energy and a nitrogen-source for biomass cultivation. These ways
48
49 of valorisation can be beneficial for the biodiesel production process, and also for other
50
51 process which extract valuable compounds from microalgae. Additionally to the
52
53 possibility of converting the LEM into methane, the co-digestion with sewage sludge
54
55 demonstrated the viability of the co-digestion process. The co-digestion of LEM and
56
57
58
59
60

1
2
3 sewage sludge allows taking advantage of the over-sized digesters in some WWTPs.
4
5 The pre-treatment of LEM before digestion resulted unsuitable for microalgae wastes,
6
7 probably due to the cell wall characteristics which hamper degradation. For this reason,
8
9 powerful pre-treatment methods should be evaluated to increase the biodegradability of
10
11 the biomass.
12

13
14 Another alternative for LEM valorisation is the conversion into bio-oil. The results
15
16 revealed the possibility to obtain high bio-oil yields. Moreover, recycling the aqueous
17
18 phase generated during HTL to the microalgae cultivation unit, the amount of fertilisers
19
20 for cultivation is reduced. The high nutrient content in the aqueous phase is problematic
21
22 for water discharge, thus the microalgae cultivation can contribute to accomplish the
23
24 regulation for water discharge.
25

FIGURE CAPTIONS

Figure 1. Scheme of the processing routes evaluated for the valorisation of the LEM. **1-column fitting image.**

Figure 2. Procedure for the separation of the different products fraction from HTL. **1-column fitting image.**

Figure 3. Growth curves in semi-logarithmic scale for *N. gaditana* in several culture media. **1-column fitting image.**

Table 1. Ultimate methane production from LEM LEW. Batch reactors at 33°C and 29 days digestion. **Note:** These experiments were not done simultaneously, thus the methane production from LEM LEW samples differs in some of the experiments.

Experiment	Substrate	SIR	CH ₄ mL _{CH₄} /g _{VS}
<i>Effect of washing</i>	Unwashed LEM	1:4	269±6
		1:2	268±17
		1:1	273±6
	Washed LEM	1:4	192±16
		1:2	185±9
		1:1	180±11
<i>Aco-D</i>	LEM	1:2	274±4
	25% Sludge	1:2	293±3
	50% Sludge	1:2	319±4
	75% Sludge	1:2	345±10
	100% Sludge	1:2	360±12
<i>Ultrasonic pre-treatment</i>	LEM	1:2	274±4
	28 MJ/kg _{TS}	1:2	269±7
	48 MJ/kg _{TS}	1:2	299±6
	55 MJ/kg _{TS}	1:2	294±4
<i>Combined pre-treatment: US and NaOH</i>	LEM	1:2	286±8
	17 MJ/kg _{TS}	1:2	289±3
	pH 9	1:2	309±6
	pH 11	1:2	300±9
	pH 13	1:2	290±5
	US + pH 9	1:2	290±3
	US + pH 11 ^a	1:2	244±4
US + pH 13	1:2	296±3	

^a Experimental error confirmed by analysis at the end of the experiment.

Table 2. Mass balance of HTL, and C and N recovery from the LEW.

	Bio-oil	AP-HTL	Gas	Solid fraction
Mass balance (g/100g _{LEM})	28±2	24±2	27±3	21±2
C recovery (% of the C in LEW)	48±4	26±1	14±1 ^a	9±2
N recovery (% of the N in LEW)	24±2	56±1	- ^b	3±1

^a Only the amount of CO₂ determined in the gas was considered.

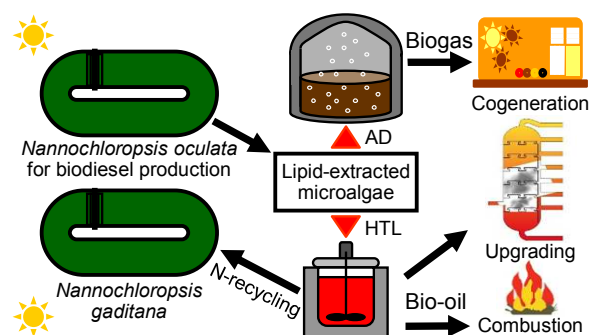

^b The N content in gas was not analysed.

Table 3. N source in the culture media and summarised results obtained during cultivation.

		Media					
		f/2 ⁺	HTL7	HTL15	HTL30	HTL45	HTL60
Source of N (mg N/L)	<i>NO₃⁻ from f/2⁺</i>	60	53	45	30	15	0
	<i>NH₄⁺ from AP-HTL^a</i>	0	7	15	30	45	60
	<i>Total Inorganic N</i>	60	60	60	60	60	60
<i>k</i> (duplications/day)		0.95±0.03	0.97 ±0.11	1.04±0.02	0.97 ±0.07	0.79±0.02	0.54±0.02
Initial pH		8.1	7.4	7.8	8.3	8.2	8.3
Final pH		9.8±0.1	9.7±0.1	9.9±0.0	9.6±0.0	9.1±0.0	7.8±0.1

^a the amount of NO₃⁻ was negligible in the AP-HTL
