## Abstract

**Background:** Game-based science learning (GBSL) provide an alternative route for learning genetics, but its effects on students' conceptual learning is contested. In this paper we assess the utility, in primary teacher education, of Recal: a game designed to promote participants' learning of key genetic concepts through acting as detectives investigating a case.

**Purpose:** The purpose of the study was to analyse and compare teacher students' learning of genetics through the game, and both their attitudes towards and experiences of it. Tests were conducted in Spanish and Swedish contexts to assess its potential utility in contrasting cultural and educational contexts to obtain indications of the potential breadth of its application.

**Samples:** Participants included 120 pre-service teacher students from a university in north-eastern Spain and 51 from a university in western Sweden.

**Design and methods:** The research involved an intervention, in which students played the game, and assessment of its efficacy by questionnaires designed to investigate students' knowledge of genetics before and after the game, their expectations and experience of it, and their satisfaction with it. The results were analysed statistically.

**Results:** The game appeared to enhance both Spanish and Swedish participants' knowledge of genetics, and they reportedly found it both educationally beneficial and

1  
2  
3 engaging. It was also assessed in terms of the following characteristics of GBSL, based  
4  
5  
6 on experiential data: contextualisation, authenticity, collaboration, problem-solving,  
7  
8  
9 guided paths and competition.

10  
11  
12 **Conclusion:** The results clearly indicate that the game has utility in different countries  
13  
14  
15 and educational contexts. The article discusses how the six characteristics of GBSL  
16  
17  
18 facilitate or hinder learning, and implications (for educational professionals and  
19  
20  
21 researchers) of the findings.

### 43 44 45 **Introduction**

46  
47  
48 In recent decades there has been a revolution in biological and genetic research leading to  
49  
50  
51 exponential increases in knowledge and new technological applications (Chen, Chu, Lin  
52  
53  
54 and Chiang 2016). The rapid consequent development of modern biotechnology and  
55  
56  
57 genetic engineering has led to huge gaps between the scientific community's and general  
58  
59  
60 public's understanding of the risks and benefits of using the new technologies  
(Boerwinkel, Yarden and Waarlo 2017). However, in order to involve society in

1  
2  
3 formulation of policies about scientific matters, we need well-informed citizens who can  
4  
5  
6 make rational decisions based on scientific knowledge and understanding of associated  
7  
8  
9 ethical and moral issues. Thus, a primary goal for science education is to help students  
10  
11  
12 develop the knowledge, skills and epistemologies required to deal with contemporary  
13  
14  
15 real-world scientific issues (Barab and Dede 2007).  
16

17  
18 For citizens to be biotechnologically literate they clearly require adequate knowledge of  
19  
20  
21 fundamental biology, including genetics (Stern and Kampourakis 2017). However, most  
22  
23  
24 members of society receive information about scientific developments in genetics through  
25  
26  
27 mass media, which may lead to lack of understanding (Kılıç and Sağlam 2014). To  
28  
29  
30 address these problems there is a clear need (corroborated by a Delphi-study involving  
31  
32  
33 international experts on genetic education and outreach) for education systems to enhance  
34  
35  
36 future citizens' genetic literacy (Boerwinkel, Yarden and Waarlo 2017). Moreover, such  
37  
38  
39 development should begin in primary education, as outlined by the US National Research  
40  
41  
42 Council (NRC 2012). To meet that goal, new teaching materials must be developed that  
43  
44  
45 enable teachers with little training in genetics to participate in enhancement of their  
46  
47  
48 pupils' understanding (Marbach-Ad et al. 2008). Game-based learning has been identified  
49  
50  
51 as a powerful approach to promote learning of content knowledge, according to several  
52  
53  
54 reviews (e.g. Chen et al. 2018; Hussein et al. 2019; Spires et al. 2019). However, few  
55  
56  
57 games have been developed to facilitate genetics education, there have been few studies  
58  
59  
60 on their potential utility, and they have provided conflicting results. Anetta et al. (2009)

1  
2  
3 detected no effects of game-based learning on genetic knowledge, Kim et al. (2015)  
4  
5  
6 detected some minor impact, and Rachmatullah (2021) recently found it can have  
7  
8  
9 significant effects on students' conceptual understanding of genetics. These discrepancies  
10  
11  
12 clearly indicate that there are poorly understood influential factors that may help or hinder  
13  
14  
15 game-based learning in genetics. These issues are explored here in an analysis of  
16  
17  
18 responses to, and effects of, features of a game called Recal that is intended to foster  
19  
20  
21 understanding of key genetic concepts.  
22  
23  
24  
25  
26  
27

## 28 **Background**

### 29 *Describing Game-based Science Learning*

30  
31  
32  
33  
34 Recal combines game characteristics such as problem-solving and authenticity for the  
35  
36  
37 purpose of engaging students in learning genetics. Game-based teaching specifically  
38  
39  
40 focused on science education has been called Game-Based Science Learning (GBSL)  
41  
42  
43 (Chen, Lui and Shou 2018; Li and Tsai 2013), and as we focus on genetics education in  
44  
45  
46 this article we use the term GBSL hereafter.  
47  
48

49  
50 Although games can support learning in various ways, there is little consensus regarding  
51  
52  
53 the definition of a game, nor GBSL (Liu et al. 2014). Related terms (such as games,  
54  
55  
56 computer games, and video games) have often been used interchangeably (O'Neil,  
57  
58  
59 Wainess and Baker 2005; Liu et al. 2014). In a seminal work, James Gee (2008) describes  
60

1  
2  
3 games as tools for “deep learning” through creation of “virtual experiences centered on  
4  
5  
6 problem solving [that] recruit learning and mastery as a form of pleasure” (p. 36). Hence,  
7  
8  
9 games can provide students with opportunities for experiential, authentic learning (Gee  
10  
11  
12 2003), and Gee (2008, p. 36) further argues that games can promote acquisition of  
13  
14  
15 knowledge within specific contexts by relating the language used in them to “actual  
16  
17  
18 experiences, actions, functions, and problem solving”.

19  
20  
21 In the literature GBSL is often described as facilitating learning by guiding learners  
22  
23  
24 through a path of events and into a way of thinking. GBSL may have several  
25  
26  
27 characteristics that foster learning, including collaboration between multiple players,  
28  
29  
30 problem-solving and competition (Chen, Lui and Shou 2018). Another characteristic of  
31  
32  
33 games applied in Science Education is that they are often designed to encourage students  
34  
35  
36 to create identities and play roles of authentic professionals, such as scientists (Van der  
37  
38  
39 Wal et al. 2016). According to GBSL theory, learning occurs when the relationship  
40  
41  
42 between actions of a player and outcomes of the system in a game are discernable and  
43  
44  
45 integrated into the game’s larger context (Rachmatullah et al. 2021). This prompts  
46  
47  
48 students to acquire information from many sources and make decisions quickly, deduce a  
49  
50  
51 game’s obstacle, understand complex systems through experimentation, and collaborate  
52  
53  
54 with others (Chen, Lui and Shou 2018).

55  
56  
57 Theoretically, a game applied in GBSL should also ideally involve multiple tools and  
58  
59  
60 resources. These resources may establish certain aspects of the game, such as the goal, the

1  
2  
3 virtual setting, rules, clues, and cycles of choices that allow players to interact with the  
4  
5  
6 environment (Liu et al. 2014). Moreover, the resources of educational games may include  
7  
8  
9 newspaper articles, videos, multi-media documents, websites, manuals, encyclopedias  
10  
11  
12 and even books for players to read in order to gain more background information and  
13  
14  
15 richer contexts for play (Cheng et al. 2015; Solé-Llussà et al. 2018). Most GBSL games  
16  
17  
18 available today, and discussed in the literature, are largely or entirely digital (e.g. Chen,  
19  
20  
21 Wang, Kirschner & Tsai, 2018; Hussein et al., 2019). However, this study is based on a  
22  
23  
24 physical game including real artefacts and paper-and-pencil tasks, thus it could potentially  
25  
26  
27 provide additional insights that may not be afforded by further analysis of digital games.  
28  
29

### 30 ***Evaluating Game-based Science Learning***

31  
32  
33 According to a systematic review by Hussein et al. (2019) most evaluations of serious  
34  
35  
36 educational games (SEGs, i.e. games that are explicitly used as teaching and learning  
37  
38  
39 tools; Annetta 2008) have assessed cognitive gains, such as content knowledge or skills,  
40  
41  
42 and attitudinal outcomes (towards the games or game environments). The overall idea is  
43  
44  
45 that GBSL provides a motivational edge in comparison to traditional teaching, and the  
46  
47  
48 game will lead to an immersive experience, what Cheng, She and Annetta (2014) describe  
49  
50  
51 as an “immersive state, whereby players become cognitively and emotionally absorbed”  
52  
53  
54 (p. 248). This immersive state is then supposed to promote better learning of curriculum  
55  
56  
57 knowledge included in the serious game than traditional teaching. If so, when assessing  
58  
59  
60 the effect of a SEG it is important to evaluate not only the cognitive gain (in this case

1  
2  
3 genetics knowledge) but also its affective effects. However, according to Cheng, She and  
4  
5  
6 Annetta (2014, p. 233) “most of the past research generally examines the issue of what  
7  
8  
9 are the cognitive and affective consequences of using SEGs. Yet, there is still a lack of  
10  
11  
12 research attempting to delve into the questions about how players feel and what they  
13  
14  
15 experience through playing SEGs.” Their point is that the assessment instruments should  
16  
17  
18 be adapted to the game evaluated, and general attitudinal instruments decoupled from the  
19  
20  
21 game should be avoided. Thus, in the study presented here, we have used both closed and  
22  
23  
24 open-ended questions to investigate players’ experiences of the Recal game, in addition to  
25  
26  
27 their content knowledge of genetics before and after playing it.

28  
29  
30 It is also important to recognize that the support for theoretical advantages of game-based  
31  
32  
33 learning claimed in some empirical studies has been questioned. For example, Kirschner  
34  
35  
36 and Van Merriënboer (2013) have asked whether learners using games really know what  
37  
38  
39 is most beneficial for their learning, and (for example) the true value of positive  
40  
41  
42 experiences. Several systematic reviews provide some illumination regarding this issue.  
43  
44  
45 In a quantitative meta-analysis of 32 articles by Vogel et al. (2006) it is concluded that  
46  
47  
48 learners who used digital learning games obtained greater cognitive gains and  
49  
50  
51 demonstrated better attitudinal outcomes, on average, than students who learned via a  
52  
53  
54 traditional teaching method. Similarly, in other systematic reviews Connolly et al. (2012)  
55  
56  
57 and Boyle et al. (2016) concluded that SEGs promote students’ content learning.  
58  
59  
60 However, in a synthesis of 39 studies, Wouters et al. (2013) found no evidence that SEGs

1  
2  
3 were more motivational than traditional teaching methods. More recently, a systematic  
4  
5  
6 review by Hussein et al. (2019) concluded that digital GBSL shows “promising  
7  
8  
9 potential...particularly in the area of content understanding”, but “the findings...also  
10  
11  
12 suggest that there is a need to provide additional research in order to gain a more  
13  
14  
15 comprehensive picture of the educational effectiveness” (Hussein et al. 2019, p. 62465) of  
16  
17  
18 GBSL. In this study we address this need by investigating if (and if so how) a specific  
19  
20  
21 SEG intended to facilitate genetics education that promotes content learning, fosters  
22  
23  
24 positive experiences and thus creates a pedagogically valuable environment.  
25

### 26 27 *A new educational game for genetics education*

28  
29  
30 Genetic literacy is recognized as crucial for the ability to take personal decisions and  
31  
32  
33 participate in democratic decision-making at socio-political levels regarding issues such  
34  
35  
36 as genetically modified organisms, genetic testing, and personal genomics (Boerwinkel,  
37  
38  
39 Yarden and Waarlo 2017). However, research has consistently shown that genetics is  
40  
41  
42 difficult to understand, and there are many misconceptions, as previously reviewed  
43  
44  
45 (Authors 2014). Genetics has also been identified by biology teachers as the most difficult  
46  
47  
48 topic to teach and learn in biology education (Bahar, Johnstone, and Hansell 1999). For  
49  
50  
51 example, Marbach-Ad and Stavy (2000) found that pre-service teachers clearly  
52  
53  
54 compartmentalized genetic concepts, and lacked coherent understanding. Another study  
55  
56  
57 found that pre-service teachers are aware of some applications of biotechnology but lack  
58  
59  
60 knowledge of basic genetic concepts (Authors 2015a). For example, students participating

1  
2  
3 in the cited study had difficulties understanding the difference between genetic  
4  
5  
6 information and genetic material, and that the same genetic information is present in all  
7  
8  
9 cells of a living organism. Moreover, these (and other) misconceptions seem to be widely  
10  
11  
12 shared by students in many countries (Authors 2014). Hence, teachers seem to have  
13  
14  
15 difficulties in equipping students with adequate genetic knowledge. There are several  
16  
17  
18 possible reasons for this. One is the dominance of traditional teaching methods focusing  
19  
20  
21 on obsolete Mendelian concepts in genetics education (Dougherty et al. 2011; Authors  
22  
23  
24 2014; Authors 2015b). Another is that teachers might not have enough knowledge to  
25  
26  
27 teach the content, especially primary teachers in elementary school. This is important  
28  
29  
30 because teachers' fundamental genetic knowledge is positively correlated with their self-  
31  
32  
33 confidence to teach the subject and ability to answer pupils' questions correctly (Stern  
34  
35  
36 and Kampourakis 2017).

37  
38  
39 Learning games have been proposed as means to overcome these teaching and learning  
40  
41  
42 difficulties in genetics education (Marbach-Ad, Rotbain & Stavy, 2008). However, few  
43  
44  
45 games have specifically targeted genetics education, there have been few studies of  
46  
47  
48 GBSL's ability to promote genetic knowledge and literacy, and those studies have  
49  
50  
51 provided conflicting results. ~~Anetta et al. (2009) detected no effects of game-based~~  
52  
53  
54 ~~learning on genetic knowledge, Kim et al. (2015) detected some impact, and~~  
55  
56  
57 ~~Rachmatullah (2021) recently identified significant effects on students' conceptual~~  
58  
59  
60 ~~understanding of genetics.~~ Thus, there is a paucity of studies exploring the role of games

1  
2  
3 in genetics education. Moreover, the few studies that have been published have focused  
4  
5  
6 on digital games, while this study addresses a physical game. Hence, this study fills  
7  
8  
9 important gaps in previous research.

10  
11  
12 Based on the above arguments, an educational game (Recal) was developed to help  
13  
14  
15 students to encounter and acquire understanding of key genetic concepts in contemporary  
16  
17  
18 contexts underpinned by GBSL theory (Authors 2017). The Recal game has been  
19  
20  
21 designed as a collaborative activity in which students work in groups of three or four for  
22  
23  
24 90-120 minutes (depending on the students' problem-solving skills) as police detectives  
25  
26  
27 investigating a criminal case. The main goal of the game is for students to acquire,  
28  
29  
30 understand and apply evidence and clues obtained in the investigation to enable them to  
31  
32  
33 complete tasks that require application of genetic knowledge. In that manner, the game is  
34  
35  
36 intended to facilitate the players' learning of genetics while not requiring any pre-  
37  
38  
39 knowledge.

40  
41  
42 The aim of the Recal game is to foster *contextualized* understanding of contemporary  
43  
44  
45 genetics concepts by immersing students in an *authentic* scientific-based scenario in  
46  
47  
48 which they play the role of a scientific assessor. They must develop and use scientific  
49  
50  
51 reasoning and evidence-based decision-making in a *collaborative way to solve problems*  
52  
53  
54 they encounter as the game progresses (Authors 2017). The game involves four phases, in  
55  
56  
57 each of which the participants receive information on specific cards about concepts  
58  
59  
60 involved in the application of forensic evidence as a *path or guiding tool*. In each phase

1  
2  
3 they must then answer a multiple-choice questionnaire before trying to solve a puzzle to  
4  
5  
6 acquire evidence (clues) collected from the scene of a robbery and results of laboratory  
7  
8  
9 tests, which helps them to eliminate some suspects (Figure 1). *Competition* to get the  
10  
11  
12 highest marks on the questionnaires also provides a motivational target for the groups. As  
13  
14  
15 can be seen from this short overview, the Recal game is designed to include the GBSL  
16  
17  
18 characteristics of contextualisation, authenticity, collaboration, problem-solving, guided  
19  
20  
21 paths and competition. For a more detailed description of the game, see Authors (2017).  
22  
23

30

### 31 ***The comparative perspective - The Spanish and Swedish contexts***

32  
33  
34 The utility of the Recal game was assessed by inviting both Spanish and Swedish  
35  
36  
37 elementary pre-service teachers with little experience and training in biology to play the  
38  
39  
40 game and evaluating (through questionnaires) their expectations and experiences of it,  
41  
42  
43 and their satisfaction with it. The educational outcome was also assessed to compare its  
44  
45  
46 learning potential in the two contrasting educational and cultural settings. The reason for  
47  
48  
49 testing the game in two different contexts is that students' understanding of educational  
50  
51  
52 games and their learning effects may depend on both educational and cultural contexts  
53  
54  
55 (Hussein et al. 2019). Therefore, in this study the game was assessed in two contrasting  
56  
57  
58 contexts: primary school teachers' educational settings in Spain and Sweden to obtain at  
59  
60  
least preliminary indications of the game's efficacy in multiple contexts.

1  
2  
3 Spain and Sweden are representatives of northern and southern European countries,  
4  
5  
6 respectively, with substantial differences in knowledge related to genetics issues. Spain is  
7  
8  
9 reportedly in the bottom four and Sweden in the top three European countries in terms of  
10  
11  
12 shares of citizens who are well informed about biotechnological applications of genetics,  
13  
14  
15 respectively, according to the latest available comparative data (European Commission  
16  
17  
18 2010). Further, teachers' perception of teaching differ between the two contexts (Loinaz  
19  
20 2019), and a recent study found differences in biotechnological literacy between pre-  
21  
22  
23 service teachers of the two contexts (Author, 2021). Hence, we regarded these contexts as  
24  
25  
26 good settings for testing the Recal game's efficacy.  
27  
28

### 30 **Aim**

31  
32  
33 The aim of the study was to assess the Recal game's utility for improving pre-service  
34  
35  
36 teachers' understanding of genetics and their attitudes towards it in two contrasting  
37  
38  
39 (Spanish and Swedish) cultural and educational settings. The study was guided by the  
40  
41  
42 following research questions:  
43  
44

- 45 1) Does participation in the Recal game promote learning of genetics?
- 46  
47 2) What GBSL characteristics of the learning game promote and hinder learning  
48  
49  
50 according to the participants?
- 51  
52 3) Are there any differences in learning outcomes and experiences between Spanish  
53  
54  
55 and Swedish participants?  
56  
57  
58  
59  
60

## Materials and methods

### *Research design*

The Recal game and associated factors were evaluated in an intervention study with a mixed methods approach designed to enable capture of both general comparative insights and more detailed and nuanced perspectives (Creswell 2014). The study combined acquisition and analysis of quantitative Likert-scale data on genetic knowledge and attitudinal experiences of the game with qualitative data obtained from an open-ended questionnaire on students' experiences of, and satisfaction with, the game.

During the intervention the students played the game, and its efficacy was assessed by questionnaires designed to acquire socio-demographic data and students' knowledge of genetics before and after the game, their expectations and experience of it, and their satisfaction with it (Figure 2). The pre-intervention questionnaire (which was manually distributed to the groups of participants by the first author) included questions on the students' socio-demographic status, genetic knowledge, and expectations regarding the learning game. After an intentional 2-week delay, the first author conducted the intervention (Recal game) with the student groups during time scheduled for a course that was not related to genetics or the game. In each case the intervention took 90-120 minutes. The post-intervention questionnaire (manually distributed to the groups of participants by the first author two weeks after the intervention) included the same socio-demographic questions and genetics questions as in the first questionnaire. It also included questions about the pre-service teachers' experience of, and satisfaction with, the game. The delay between the intervention and post-testing was deliberately included to test the GBSL activity's persistent, rather than immediate, effects (Figure 2).

[Insert Figure 2 about here]

### ***Participants***

Two samples of pre-service primary teachers were recruited for the study, because they had limited pre-knowledge of genetics but would have responsibility for teaching children biology, including genetics, in the future. Thus, they were typical target groups for the Recal game. The first sample consisted of 120 pre-service teacher students (four classes of 20-30 students) from a university in north-eastern Spain. The students were taking an experimental science course that was part of their second level primary school teacher education program. The second sample consisted of 51 pre-service teachers (two classes of 20-30 students) from a university in western Sweden. Students were taking a general science course that was part of their primary teacher education program. It should be noted that the Spanish and Swedish curricula for primary teacher education do not include specific university courses in biology, but biology content is included in the abovementioned science courses.

The study followed the local ethical guidelines in both countries, *inter alia* the respondents were fully informed about the content of the study that participation was voluntary, and they could withdraw at any time. Consent was collected from the participants, and all acquired data have been treated with confidentiality and solely for research purposes.

### *Instruments*

The questionnaires used in the study included five instruments. First, a set of socio-economic questions to acquire background information about the participants. Second, 10 items designed to measure genetic knowledge before and after the intervention, thereby addressing the first research question. The other three were reflective attitudinal instruments developed from the literature to assess the students' expectations of the game pre-intervention and both their experiences of and satisfaction with its post-intervention, thereby addressing the second research question. These instruments are described in the following sections.

- Socio-demographic data

These items consisted of one question for coding the participant, and three regarding socio-demographic variables (their age, gender and parents' educational level), as shown in Table 1. These three items were only included in the pre-intervention questionnaire. Sociodemographic data were collected to characterize both samples of students, and thus assess their comparability.

- Genetic knowledge test

Ten multiple-choice (True, False or Do not know) questions were designed to test participants' basic knowledge of genetics, matching specific intended learning outcomes

1  
2  
3 from the Recal game intervention. These items were included in both the pre- and post-  
4  
5  
6 intervention questionnaires (Tables 2 and 3) and were collected from author (2015b).  
7  
8  
9

- 10 • Expectation questions  
11  
12

13 Three attitudinal questions regarding the participants' perceptions and expectations before  
14  
15 participating in the Recal game were developed (Table 4) and included solely in the pre-  
16  
17 intervention questionnaire.  
18  
19  
20  
21  
22

- 23 • Experiences of and satisfaction with the game – part 1  
24  
25

26 A new instrument was developed to measure the students' experiences of and satisfaction  
27  
28 with the game based on an instrument developed by Garrido (2005). This consists of 29  
29  
30 closed questions inviting Likert-type responses (strongly agree, agree, disagree, or  
31  
32 strongly disagree) regarding five aspects of the intervention (organization and structure of  
33  
34 the game, group working environment, motivation, student assessment, and future  
35  
36 applications). These items (which were only included in the pre-intervention  
37  
38 questionnaire) and associated aspects are presented in Table 5.  
39  
40  
41  
42  
43  
44  
45  
46

- 47 • Experiences of and satisfaction with the game – part 2  
48  
49

50 To further investigate the students' experiences of and satisfaction with the game an  
51  
52 open-ended questionnaire adapted from Biasutti (2011) was included. This invites  
53  
54 participants to note, in writing, three aspects of the Recal game that they would like to  
55  
56  
57  
58  
59  
60

1  
2  
3 keep, three they would like to eliminate and three they would like to change. These items  
4  
5  
6 (presented in Tables 6 and 7) were only included in the post-intervention questionnaire.  
7  
8

### 9 10 *Statistical analysis*

11  
12 First the reliability of the instruments was assessed by calculating Cronbach's alpha  
13  
14 coefficients. We then calculated descriptive statistics for participants' responses to the  
15  
16 three questionnaire scales with closed questions and assessed the significance of between-  
17  
18 group differences in responses using paired-sample t tests and repeated-measures  
19  
20 Analysis of Variance (ANOVA) with a General Linear Model (GLM).  
21  
22  
23  
24  
25  
26  
27

### 28 *Analysis of responses to the open questions*

29  
30  
31 An inductive approach was employed to analyse and categorize responses to the three  
32  
33 open questions in the last section of the post-intervention questionnaire, based on the  
34  
35 following five phases of the 'constant comparative method' (Strauss and Corbin 1998).  
36  
37 First, immersion, in which all the discernibly different answers are recognized. Second,  
38  
39 categorization, in which 'categories' are identified in the discernibly different answers.  
40  
41 Third, phenomenological reduction, in which 'themes' emerge from the 'categories'.  
42  
43 Fourth, triangulation, in which supplementary aspects are used to corroborate, amend  
44  
45 and/or refine researchers' interpretations. Finally, in interpretation, a complete  
46  
47 explanation of outcomes is sought based on the interpretations in conjunction with  
48  
49 previous research and/or models. The coding of the open questions was subsequently  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 validated by an independent researcher who separately checked the data coding. The first  
4  
5  
6 author and the independent researcher addressed any disagreements regarding their  
7  
8  
9 coding and through a process of negotiation reached 100% agreement.  
10

11  
12 Finally, categories were weighted by frequencies of responses in which they appeared of  
13  
14  
15 participants of each group from each country.  
16

## 17 18 19 **Results**

20  
21  
22 In this section we first present demographic data on our samples of Spanish and Swedish  
23  
24  
25 pre-service teacher students. These are means and standard deviations (in  $x \pm y$  format) or  
26  
27  
28 frequencies of the students' age, gender, and parents' educational level.  
29

30  
31  
32 [Insert Table 1 about here]  
33

34  
35 As shown in Table 1, the Spanish students were younger on average than the Swedish  
36  
37  
38 students ( $21.1 \pm 3.53$  and  $28.3 \pm 7.99$  years, respectively). Hence, the Swedish students  
39  
40  
41 may have had more professional or academic experience before they entered teacher  
42  
43  
44 training. There were higher shares of females than males in both the Spanish and Swedish  
45  
46  
47 groups (79 and 91%, respectively), reflecting the dominance of women in primary teacher  
48  
49  
50 education in both countries. The Swedish students generally had more highly educated  
51  
52  
53 parents than the Spanish students. In summary, the demographic data indicate that the  
54  
55  
56 Swedish students may generally have had higher educational levels, and potentially more  
57  
58  
59  
60

1  
2  
3 pre-intervention knowledge of genetics and/or relevant contexts than the Spanish  
4  
5  
6 students.

7  
8  
9  
10 Cronbach's alpha coefficients, calculated to assess the instruments' reliability, ranged  
11  
12 between .89 and .96, indicating good reliability. In the following sections we present the  
13  
14  
15 results pertaining to each of the research questions addressed in the study.

16  
17  
18 ***Does participation in the Recal game promote learning of genetics?***  
19

20  
21  
22 To assess the game's ability to promote students' learning of genetics, we compared total  
23  
24 pre- and post-intervention scores (obtained by assigning one point for each correct answer  
25  
26 to the genetic knowledge questions and summing scores for all students of both  
27  
28 countries). The post-intervention scores were significantly higher, by more than two  
29  
30 points, on average, than the pre-intervention scores:  $6.09 \pm .87$  and  $3.87 \pm 2.03$ ,  
31  
32 respectively;  $t(126) = 11.35$ ,  $p < 0.001$ . Furthermore, there were significant ( $p < 0.05$ )  
33  
34 improvements in scores for all questions (Table 2), except question 3, for which there was  
35  
36 a marginally significant improvement ( $p = 0.07$ ).  
37  
38  
39  
40  
41  
42  
43  
44  
45

46 [Insert Table 2 about here]  
47  
48

49 The next step was to investigate variations in the improvement in genetic knowledge. The  
50  
51 Spanish students' post-intervention scores were 2.66 points higher than their pre-  
52  
53 intervention scores on average ( $6.12 \pm 1.90$  and  $3.46 \pm 1.90$ , respectively). The Swedish  
54  
55 students had higher pre-intervention scores on average ( $5.03 \pm 1.93$ ) than the Spanish  
56  
57  
58  
59  
60

1  
2  
3 students, but there was just a one-point increase in their scores (to  $6.03 \pm 1.81$ ) following  
4  
5  
6 the intervention. The significance of the differences between pre- and post-intervention  
7  
8  
9 scores between the two samples was confirmed by 2x2 repeated measures analysis,  
10  
11  
12 including time (pre- and post-intervention) and sample (Spanish and Swedish) factors.  
13

14  
15 In addition, between-sample differences in pre- and post-intervention scores for each  
16  
17  
18 question were examined. The results are presented in Table 3 and summarized here. In the  
19  
20  
21 pre-intervention test, only two questions were correctly answered by more than 50% of  
22  
23  
24 the Spanish teacher students (questions 2 and 9, which were correctly answered by 79 and  
25  
26  
27 82% of the students, respectively). Three questions were correctly answered by more than  
28  
29  
30 50% of the Swedish students (questions 2, 9 and 10, by 91, 88 and 70% of the students,  
31  
32  
33 respectively). Moreover, higher shares of the Swedish students than the Spanish students  
34  
35  
36 correctly answered nine of the 10 questions. In contrast, higher percentages of the  
37  
38  
39 Spanish students gave 'Do not Know' answers in the pre-intervention test, indicating  
40  
41  
42 awareness of their ignorance of corresponding genetic concepts. In the post-intervention  
43  
44  
45 test, seven and six of the questions were correctly answered by more than 50% of the  
46  
47  
48 Spanish and Swedish students, respectively. In addition, in the post-intervention test the  
49  
50  
51 Spanish students correctly answered the questions that elicited 'Do not Know' answers  
52  
53  
54 from them in the pre-intervention test.  
55

56  
57 Although the increase in the Spanish students' correct answers was significant for all  
58  
59  
60 questions (see Figure 3A), more than half still wrongly answered three of them (3, 4 and

1  
2  
3 8) in the post-intervention test. In contrast, the increases in correct responses by the  
4  
5 Swedish participants to specific items were not significant, except for questions 5 and 6  
6  
7 (Figure 3B). Similarly, less than half of them did not correctly answer four questions (3,  
8  
9 4, 5 and 8), three of which were in the corresponding set for Spanish students. Two of  
10  
11 these items, questions 3 and 4 (inviting responses to the statements *DNA molecules are*  
12  
13 *the same in all living beings* and *Chromosomes are made up of cells*, respectively) refer to  
14  
15 genetic concepts concerning DNA structure and cell management of genetic information.  
16  
17  
18  
19  
20  
21  
22  
23

24 [Insert Table 3 about here]

25  
26  
27 [Insert Figure 3 about here]

### 28 29 30 ***Participants' experience of aspects of the game that promoted and hindered learning***

31  
32  
33 The attitudes of students towards the Recal game before the activity were assessed using  
34  
35 three expectation items in the pre-intervention test. The results indicate that, in both  
36  
37 countries, 79% of students had great expectations about the activity and 85% expected it  
38  
39 to be dynamic and motivating (Table 4). In addition, 88 and 91% of the Swedish and  
40  
41 Spanish students agreed or strongly agreed that the activity would help to improve their  
42  
43 knowledge. Thus, the students had high expectations before participating in the game.  
44  
45  
46  
47  
48  
49

50  
51 Students' self-evaluated satisfaction with the game was quantitatively evaluated by 29  
52  
53 items in the post-intervention test covering five aspects of the game: *its organization &*  
54  
55 *structure, group working environment, motivation, student assessment of the activity and*  
56  
57  
58  
59  
60

1  
2  
3 *future applications of the activity* (Table 5). Both the Spanish and Swedish participants  
4  
5  
6 expressed positive responses to all five of the mentioned aspects, as illustrated by the  
7  
8  
9 following examples. More than 80 and 70% of the Spanish and Swedish students,  
10  
11  
12 respectively, agreed that the main goals of the activity were comprehensible and that its  
13  
14  
15 pacing and police case topic were appropriate and interesting. Around 90% of participants  
16  
17  
18 in both countries agreed that the game was motivating, dynamic, clear and well  
19  
20  
21 organized. Most participants of both countries also agreed that the educational material  
22  
23  
24 was helpful and that the group working atmosphere was satisfactory. They also expressed  
25  
26  
27 a preference for teamwork and indicated that they had learned from other team members.  
28  
29  
30 The pre-service teachers also assessed the activity from a learning perspective. Most of  
31  
32  
33 the Spanish and Swedish students declared that the GBSL activity was a good way to  
34  
35  
36 learn and acquire new knowledge and that they would like to engage in such activities  
37  
38  
39 more often. More than 90 and 73% of them, respectively, declared that the Recal game  
40  
41  
42 had met their expectations. Similarly, around 90% of both samples stated that they would  
43  
44  
45 recommend the activity to other students.

46  
47  
48 [Insert Table 4 about here]

49  
50  
51 [Insert Table 5 about here]

52  
53  
54 The last part of the post-intervention questionnaire invited students to suggest sets of  
55  
56  
57 three aspects of the game that they would keep, change, and eliminate. The responses  
58  
59  
60

1  
2  
3 were counted, and the most frequent suggestions are presented, with percentages of the  
4  
5  
6 Spanish and Swedish students who made them, in Tables 6 and 7, respectively.  
7  
8

9  
10 [Insert Table 6 about here]  
11

12  
13 [Insert Table 7 about here]  
14

15  
16 Aspects of the Recal game that the highest shares of Spanish and Swedish teacher  
17  
18 students would reportedly keep were the same: “teamwork” (25 and 26%, respectively)  
19  
20 followed by ‘police case’ (17 and 15%, respectively) and ‘use of additional information  
21  
22 cards’ (12 and 13%, respectively). However, there were some substantial variations in the  
23  
24 two samples’ responses. Most prominently, 12% of the Swedish students (but none of the  
25  
26 Spanish students) highlighted the motivational quality of the GBSL activity. In contrast,  
27  
28 11% of the Spanish students (but none of the Swedish students) approvingly mentioned  
29  
30 the Recal game’s structure.  
31  
32  
33  
34  
35  
36  
37  
38  
39

40 Regarding aspects that students thought should be changed, nearly a fifth of the Swedish  
41  
42 students (19%) stated that the instructions should be clearer at the start of the game. A  
43  
44 similar share of the Spanish students (16%) advocated inclusion of more supplementary  
45  
46 information cards and more information on each card to help participants solve the case.  
47  
48  
49 A substantial share of the Spanish students (12%) also raised timing issues. However,  
50  
51 some recommended provision of more time for the tasks, while others said that they had  
52  
53 to wait too long for other groups to complete assignments. This discrepancy might be  
54  
55 associated with differences in students’ levels of prior understanding and suggests that  
56  
57  
58  
59  
60

1  
2  
3 allowing groups to work at their own pace may be beneficial. Several suggestions were  
4  
5  
6 assigned to 'Teacher' and 'Information' categories, especially by Spanish students who  
7  
8  
9 recommended introduction of genetic contents before participation in the activity or  
10  
11  
12 provision of more information during the game.  
13  
14

15 Finally, regarding aspects of the Recal game that students would eliminate, 21% of the  
16  
17 Swedish students recommended re-organization of the game, and reduction of the  
18  
19 confusing number of worksheets. A substantial share 25% of the Spanish students also  
20  
21  
22 stated that they would eliminate some worksheets. In addition, around a quarter of the  
23  
24  
25 Swedish students stated that the content was too difficult and recommended reduction of  
26  
27  
28 the information, and 15% of the Spanish students recommended simplification of the  
29  
30  
31 game by reducing the number of activities. A general conclusion is that the Spanish  
32  
33  
34 students would have preferred a lower workload during the activity, while the Swedish  
35  
36  
37 students advocated re-organization of the materials.  
38  
39  
40  
41

42 In summary, a large majority of the Spanish and Swedish students agreed that the topic  
43  
44 based on a police case is interesting and maintains the participants' engagement in the  
45  
46  
47 activity. They also preferred working in groups to working individually. They found the  
48  
49  
50 supplementary information cards helpful for solving the police case, but substantial shares  
51  
52  
53 indicated that there is too much information to learn in a two-hour session. Thus, dividing  
54  
55  
56 the activity into two sessions or providing more time, if necessary, for groups to read and  
57  
58  
59 assimilate the information may also be helpful.  
60

## Discussion

### *Recals' ability to promote learning of genetics*

Presented results of the pre- and post-intervention tests of genetic knowledge show that the Recal game can improve the genetic knowledge of participating students. Responses of the Spanish and Swedish students to the intervention were very similar, indicating that the Recal game can be used in various contexts with similar results. The knowledge gain between the pre- and post-tests was slightly greater in Spain, but this might be due to 'ceiling effects' associated with Swedish pre-service teacher students' higher pre-intervention knowledge and pre-intervention test scores. Thus, there was less scope for the activity to improve their scores.

Results of these tests support previous findings that use of gaming methodologies in genetics teaching can provide better learning outcomes than traditional approaches (Kim et al., 2015; Rachmatullah et al. 2021; Solé-Llussà et al. 2018), but conflict with findings by Anetta et al. (2009) that GBSL has no significant effects on learning outcomes in genetics. It should be noted that our results also extend the previous findings as they are based on studies of digital gaming, while we investigated a physical game and its effects.

However, our results are not unambiguous. Participation in the Recal game substantially enhanced the students' understanding of 'transfer of information between generations', and 'differences in karyotypes between species and between males and females. In contrast, it provided limited improvement in understanding of the nature of genetic

1  
2  
3 information, and there was considerable confusion—as often found in previous studies  
4  
5  
6 (Annetta et al. 2009; Rachmatullah et al. 2021)—about basic biological structures  
7  
8  
9 (chromosomes, cells, and genes) before and after the intervention. Nevertheless, the  
10  
11  
12 detected effects of the Recal game on genetic understanding are encouraging, particularly  
13  
14  
15 given the short duration of the intervention. However, these effects are largely restricted  
16  
17  
18 to concepts that are mostly strongly targeted in the game, and to teach a broader web of  
19  
20  
21 genetic concepts the game must be complemented with other games, teaching aids or  
22  
23  
24 traditional instruction.

### 25 26 27 ***Characteristics of GBSL that facilitate or hinder learning***

28  
29  
30 We discuss here results regarding attitudinal aspects: expectations of and satisfaction with  
31  
32  
33 the game, and their relations to designed characteristics of the GBSL framework  
34  
35  
36 (contextualisation, authenticity, collaboration, competition, problem-solving and guided  
37  
38  
39 paths). Overall, the teacher students' experiences were generally positive, and similar in  
40  
41  
42 both countries, indicating that the Recal game has both utility and validity. The game was  
43  
44  
45 new to the students, and the intervention was conducted as an event outside their ordinary  
46  
47  
48 teaching practice. This might have promoted a positive response due to the specific  
49  
50  
51 attention it received (Cook 1962) and/or power relations (Cohen, Manion and Morrison  
52  
53  
54 2011), so the results should be interpreted with caution. However, the open-ended  
55  
56  
57 qualitative responses provide indications of the students' reasons for their positive  
58  
59  
60 response, which corroborate the robustness of the results, and the conclusion that the

1  
2  
3 reported positive experience was due to participation in the game rather than the attention  
4  
5  
6 it received or power relations.  
7  
8  
9

10 The *contextualization* of genetics by using a forensic case as well as the *authenticity*  
11  
12 through identity-making by providing different roles in the police case was highly  
13  
14 appreciated by the students, as shown in the questionnaire responses. The students  
15  
16 claimed this increased their motivation to learn more about biotechnological applications  
17  
18 of genetic knowledge. Van der Wal et al. (2016) argued that role assignment in games  
19  
20 might be important for social learning. This is because it can putatively improve the  
21  
22 quality of solutions by including relevant non-scientific sources of knowledge and  
23  
24 experience, and by enhancing solutions' relevance and legitimacy through associated  
25  
26 provision of diverse perspectives. The findings of this study support these arguments.  
27  
28  
29 Although the use of forensic cases in genetic games is not novel, it was novel to most of  
30  
31 the participants in our study, which might partly explain the positive experiences. Hence,  
32  
33 a novelty effect cannot be excluded as a possible explanation for these positive  
34  
35 experiences.  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47

48 The presence and importance of the *collaborative* characteristic in the Recal game were  
49  
50 acknowledged in the students' responses to part 1 of the experiences of and satisfaction  
51  
52 questionnaire, which clearly indicated that they felt there was a good working atmosphere  
53  
54 during the gaming. Moreover, in responses to the open-ended questions students from  
55  
56 both countries stated that the most appreciated characteristic of the activity was working  
57  
58  
59  
60

1  
2  
3 in groups, as shown in the 'team work' category. Hence, most students, from both  
4  
5  
6 countries, felt comfortable engaging in the activity in groups, corroborating previous  
7  
8  
9 findings that collaboration is an important success factor in GBSL design (Chen, Liu and  
10  
11  
12 Shou 2018; Chen et al., 2018). Interestingly, however, the students provided little support  
13  
14  
15 for the notion that the *competitive* aspect of the game was important. This is consistent  
16  
17  
18 with findings in a recent study that students who engaged in a **competitive** intervention  
19  
20  
21 performed significantly better on a learning achievement test than peers who had engaged  
22  
23  
24 in a competitive, but otherwise identical, intervention (Chen, Liu & Shou 2018). The  
25  
26  
27 results of our study give some support for those findings. Thus, the importance and  
28  
29  
30 effects of competition clearly warrant further investigation and consideration in the  
31  
32  
33 further development of GBSL.

34  
35  
36 Almost all the participating Spanish and Swedish pre-service teacher students also agreed  
37  
38  
39 that the *problem-based learning* approach incorporated in the activity was a beneficial  
40  
41  
42 way to learn. The vast majority of both sets said that they would like to engage in such  
43  
44  
45 activities more often in their education. This is consistent with underlying theories of  
46  
47  
48 gaming as suggested by Gee (2008), and empirical findings as reviewed by Chen, Lui and  
49  
50  
51 Shou (2018) that problem-based activities in GBSL have motivational features.

52  
53  
54 Regarding the last characteristic, the *guided paths* provided by the game, our results  
55  
56  
57 indicate that most of the pre-service teachers from both countries thought that the main  
58  
59  
60 goals of the Recal game were understandable and clear. However, many students

1  
2  
3 suggested that additional information cards and more instructions could improve the  
4  
5  
6 game, clearly indicating that some students wanted more guidance or scaffolding. This  
7  
8  
9 could be at least partly due to most students in both countries having little experience of  
10  
11  
12 learning through this kind of game activity, and limited pre-knowledge of genetics. In  
13  
14  
15 future development of the Recal game, more scaffolding should be considered. However,  
16  
17  
18 if the degree of scaffolding is increased, the level of problem-based learning is decreased,  
19  
20  
21 and the optimal trade-off between the two goals must be considered. This may be an  
22  
23  
24 important finding to consider in the future development of SEGs for players with limited  
25  
26  
27 pre-knowledge and gaming skills to use in GBSL activities.

28  
29  
30 To conclude, most of the design characteristics of GBSL used to develop the Recal game  
31  
32  
33 seem to function as intended, but the competition and guided paths characteristics showed  
34  
35  
36 less alignment with intended goals for the game. Consideration of these findings might be  
37  
38  
39 useful in efforts to design, research and develop SEGs for use in future GBSL.

### ***Implications for the use and further studies of the Recal game***

40  
41  
42  
43  
44  
45 The results of this study indicate that the Recal game has the potential to promote  
46  
47  
48 genetics learning via a GBSL approach. The results show that participation in the game  
49  
50  
51 increased the pre-service teachers' knowledge and understanding of some central ideas of  
52  
53  
54 genetics. Hence, the game can enhance the genetics literacy of an important target group  
55  
56  
57 who generally have limited educational background in genetics but will be responsible for  
58  
59  
60 teaching children about the subject in the future, as called for in the literature

1  
2  
3 (Boerwinkel, Yarden and Waarlo 2017). Moreover, the attitudinal and experienced based  
4  
5  
6 results show that the students had very positive experiences during their participation.  
7  
8  
9 This is encouraging as attitudinal aspects are suggested to be very important for engaging  
10  
11  
12 in a game and hence learning from it (Cheng, She and Annetta 2014).  
13  
14

15  
16 As the results in the two different educational and cultural contexts of Spain and Sweden  
17  
18 were very similar it seems likely that the game would have similar benefits in other  
19  
20  
21 countries and educational systems. Thus, we advocate its use in other countries and  
22  
23  
24 educational contexts. However, it is also important to recognize that a rigorous  
25  
26  
27 experimental design was not applied in this study, and more evaluations of the games'  
28  
29  
30 effects are required, including comparisons with a control group. Comparisons of this  
31  
32  
33 physical game with other interventions based on digital games designed to foster learning  
34  
35  
36 of genetics would also be valuable. One interesting possibility would be to digitalize the  
37  
38  
39 Recal game then compare effects of the digital and physical versions.  
40

**Figures and Tables****Table 1***Socio-demographic data on the Spanish and Swedish participants.*

	Variable	Spanish	Swedish
Age	Age in years	21.15±3.53	28.27±7.99
Sex	Female	79%	91%
	Male	21%	9%
Parents' educational level	Elementary school certificate	31%	12%
	High school certificate	44%	46%
	University degree	25%	42%

**Table 2**

*Total scores for each genetic knowledge question in the pre- and post-intervention tests.*

Question	Pre-test	Post-test	<i>t</i>	<i>p</i>
1. The phenotype is independent of genetic information.	2.76	5.76	5.67	< .001
2. All living organisms have the same number of chromosomes.	8.27	9.84	4.36	< .001

3. DNA molecules are the same in all living beings.	2.44	3.39	1.83	.070
4. Chromosomes are composed of cells.	2.05	2.83	1.98	.049
5. We can distinguish two women by the information that we get from karyotypes.	0.79	4.72	8.50	< .001
6. We can obtain information about species, gender and some genetic diseases from a karyotype.	3.7	7.95	7.68	< .001
7. Human beings have more DNA because they are more evolved.	3.78	7.01	5.91	< .001
8. A son looks more like his father when he receives a higher percentage of genetic information from him.	2.13	3.7	3.04	.003
9. Men have one chromosome that is the same as in women and another that is different.	8.43	9.21	2.16	.032
10. A boy has 23 pairs of chromosomes. His father transmits to him one chromosome of each pair and his mother the other.	4.33	6.54	4.80	< .001

The group working atmosphere was satisfactory.	0	1	24	75	0	6	45	48
I would have preferred to do the activity on my own.	80	13	4	3	42	36	15	6
I had some problems with other team members to solve the activity.	81	16	1	2	67	21	6	6
I learned from other members of the team when I had doubts.	3	9	52	36	3	18	55	24
<b>Motivation:</b>	Strongly disagree	Disagree	Agree	Strongly agree	Strongly disagree	Disagree	Agree	Strongly agree
This activity has increased my interest in genetics and biotechnology.	9	54	35	2	15	39	45	0

This police case has motivated me to increase my knowledge about scientific topics.

15 47 37 1 18 55 27 0

I think that this activity is motivating and dynamic.

0 9 60 31 3 9 73 15

**Student assessment of the activity:**

Strongly disagree Disagree Agree Strongly agree Strongly disagree Disagree Agree Strongly agree

I think that this kind of problem-based learning activity is a good way to learn.

0 5 61 34 0 3 70 27

The research that we did to solve the police case was useful for gaining knowledge.

0 18 58 24 0 6 76 18

This activity made me learn new knowledge.

1 14 63 22 0 12 73 15

It was difficult to solve all parts of this case.
